FMU

After the models (IDU3FS and TWH3001) are built by Dymola, we can use a Python library called **FMpy** [33] in order to speed up the simulation and to launch it in our code.

FMpy [33]

FMpy is a free Python library to simulate **Functional Mock-up Units**(FMUs) that :

- supports FMI 1.0 and 2.0
- supports Co-Simulation and Model exchange
- has a command line, graphical user interface

Parameters

Parameters

3 parameters are indispensable to permit the proper functioning of the simulation : T_{set} , $\Delta T_{hysteresis}$ and H_{gauge}

- T_{set} is the maximal temperature to reach
- $\Delta T_{hysteresis} = T_{set}$ - T_{min} with T_{min} the minimal temperature to reach
- \blacksquare H_{gauge} is the height-location (from the top) of the temperarature sensor

Statistics

We work on a discretization of the possible attributes, we define the paramaters' range and design space by a cubic-grid.

Cubic-grid

Cubic-grid has $\textit{N} = 16 \times 29 \times 19 = 8816$ possible designs ^a, as :

- $T_{set} \in [315.15, 330.15]$ every 1 Kelvin degree, as $dim(\mathbb{T}_{set}) = 16$
- lacktriangle $\Delta T_{hysteresis} \in [2,30]$ every 1 degree, as $dim(\Delta \mathbb{T}_{hysteresis}) = 29$
- $lacksymbol{H}_{gauge} \in [0,0.9]$ every 0.05 meter, as $\mathit{dim}(\mathbb{H}_{gauge}) = 19$
- a. Some of these designs are not physically possible

formulation

The main optimization problem can be formulated as such :

$$\underset{u \in \mathcal{X}}{\operatorname{argmax}}(COP_{DHW}(u), stars(u))$$

where
$$\mathcal{X} = \mathbb{T}_{\textit{set}} imes \Delta \mathbb{T}_{\textit{hysteresis}} imes \mathbb{H}_{\textit{gauge}}$$

Multi-objective optimization

Multi-objective optimization problems deals with conflicting objectives. This comes from the fact that we cannot say which is "best".

Here is an example:

Thermea Project

Quentin Dumont

Introduction

Project : Optimization of a Water heater

Project reformulation IDU3FS

TWH3001

Dymola and FMU Paramaters, objectives

algorithms Evaluating parameters and algorithms

Statistics

We are interested in the following mathematical problem:

- f_m an function of objective (COP(x) and stars(x) for example)
- $\mathbf{x} = (x_1, x_2, ..., x_n)^T$ a vector $min_{\mathbf{x} \in K}(f_m(\mathbf{x})), \quad m \in \{1, 2\}, \quad K \ compact$

with constraints:

$$g_j(x) \ge 0, \quad j = 1, 2, ... n_1$$

and illustrated by:

Domination

A solution x_i dominates x_j if both condition 1 and 2 below are true :

- Condition 1 : x_i is no worse than x_i for all objectives
- Condition 2 : x_i is strictly better than x_j in at least one objective

Mathematical notation : $x_i \leq x_i$

Non-dominated solution

Among a set of solutions M, the non-dominated solutions are those that are not dominated by any member of this set. The others are so called "dominated solution"

Pareto front

the non-dominated set of solutions is called "pareto front"

Evaluating parameters and algorithms
Statistics

Metaheuristic algorithms

It is not doable to explore all possibilites in a reasonable amount of time

Main idea

The main idea behind a genetic algorithm is to consider the set of all possible parameters as a population of individuals, each with their own attributes (the parameters) and fitness (objectives). An individual is considered to be fitter than an other individual if he has better objectives.

Thermea Project

Quentin Dumont

Introduction

Project : Optimization of a Water heater

Project reformulation IDU3FS

TWH3001

Dymola and FMU Paramaters, objectives

Metaheuristic algorithms

Evaluating parameters and algorithms Statistics

In our case :

A set given of attributes $(x_1, x_2, x_3) \in \mathbb{T}_{set} \times \Delta \mathbb{T}_{hysteresis} \times \mathbb{H}_{gauge}$ is viewed as an individual with attributes (x_1, x_2, x_3) and the corresponding couple $(COP_{DHW}, stars_float)$ value is its fitness.

We will focus on particular two families of metaheuristic algorithms : **Genetic algorithms** $^{[26]}$ and **Particle swarm optimization** $^{[29]}$

Metaheuristic algorithms

Evaluating parameters and algorithms

Particle swarm optimization

Particle swarm optimization is one of the most well-known methaeuristic optimization technique based on swarm, which was proposed by Eberhart and Kennedy^[31] from 1995.

Main idea

This algorithms inspired from swarm behavior such as bird flocking in nature.

It simulates animal's social behavior and cooperative way to find food, and each member in the swarms keeps changing the search pattern according to the learning experiences of its own and other members.

Statistics

Implementation

JmetalPy¹

- Done by the JmetalPy's library ^[14]
- An object-oriented Python-base framework for multi-objective optimization with metaheuristic techniques
- Created in 2006 by Antonio Benitez-Hidalgo, Antonio J.Nebro, José Garcia-Nieto, ...

Why?

- A full redesign from scratch in 2015
- An easy use of parallel computing
- A large amount of metaheuristic algorithms.

Thermea Project

Quentin Dumont

Introduction

Project :
Optimization of a
Water heater
Project reformulation

WH3001

Dymola and FMU Paramaters, objectives

and data Metaheuristic algorithms

Evaluating parameters and algorithms

4 "candidates" of metaheuristic algorithms (2 genetic algorithms and 2 particle swarm optimization's algorithms) and 1 algorithm of random search (our comparative algorithm) in JmetalPv.

These 4 "candidates" are as follows:

- NSGA II (genetic-algorithm)
- NSGA III (genetic-algorithm)
- MOPSO (particle swarm optimization)
- SMPSO (particle swarm optimization)

Our motivation is twofold. First, we want to compare each these multi-objective optimization's algorithms consisting in analysing the performance. Secondly, we want to study the convergence speed with the idea of number of individuals computed.

aramaters, objectiv nd data

Metaheuristic algorithms

Evaluating parameters and algorithms

Termination criterion

We opted for Inverted Generational Distance (IGD) as a criteria to stop our algorithm. This measure use the true pareto front as a reference and compare each elements of the true pareto front with the pareto front returned by our algorithm.

This measure is defined by:

$$IGD = \frac{\sqrt{\sum_{i=1}^{n} d_i^2}}{n}$$

where n is the number of elements in the true pareto front and d_i , the euclidean distance between the true pareto front's points and the nearest points of the pareto front found by our algorithm. When IGD=0, all the points generated by our algorithm are in the true pareto front.

Thermea Project

TWH3001

Dymola and FMU Paramaters, objectives

Metaheuristic algorithms

Evaluating parameters and algorithms

Goal

The objective is to find the algorithm and its parameters that converge quicker to that best known individual.

Each algorithm need a specific set of parameters to be runned :

- NSGA2 : paramater p = [problem, seeds, mut_pbs, index pbs, n inits, cx pbs]
- NSGA3 : parameter p = [problem, seeds, mut_pbs, index pbs, n inits, cx pbs]
- MOPSO: parameter p = [problem, seeds, mut_pbs, perturbation,n inits]
- SMPSO : parameter p = [problem , seeds, mut_pbs, index pbs, n inits]

Metaheuristic algorithms

Evaluating parameters and algorithms Statistics

Classification

- $p = [cx_pb, mut_pb, ind_pb]$
- The number of unique individuals
- we can store the quantity
 unique_evals(alg, datafile, p, seed)
- In the end, we store a quantile (90%) of unique_evals

We can use this notation : $q_{90}(alg, datafile, p)$ (this value depends on the set of seeds that we used).

Choosing the overall best set of parameters for an algoritm I

Three different options to decide on the overall best parameter p for the algorithms alg :

- "minmax" classification
- "points" classification
- "sucess rate" classification

and algorithms Statistics

Choosing the overall best set of parameters for an algoritm II

minmax classification

For each set of parameters, we store its worst performances over all the datafiles

$$q_{90}(\mathsf{alg}, \mathsf{datafile}_{i_{\mathsf{worst}}}, p) = \max_{i=1,2} q_{90}(\mathsf{alg}, \mathsf{datafile}_i, p)$$

we take the parameter $p_{j_{best}}$

$$p_{j_{\mathsf{best}}} = \min_{j=1,\dots 175} \left(\max_{i=1,2} q_{90}(\mathsf{alg}, \, \mathsf{datafile}_i, \, p_j) \right)$$

and data

Metaheuristic algorithms Evaluating parameters and algorithms

tatistics

Second option: a "points" classification

"points" classification

For each data file datafile, we classify the sets of parameters from the one with the smallest (best) quantile to the one with the biggest (worst) quantile. With this ranking, each set of parameters gets a number of points equal to its position in the list (a high quantile is worth more points).

We then add up the points of each set of parameters accross all the data files to get a final ranking, and we choose the one which got the fewest points.

Water heater
Project reformulation

WH3001

Dymola and FMU

Paramaters, objectives and data

Metaheuristic algorithms Evaluating parameters

and algorithms Statistics

Third option: a "sucess rate" classification

"sucess rate" classification

For each data file datafile, we count the convergence's sucess rate of each sets of parameters as follows:

- $oldsymbol{\alpha}$ = sucess rate of n points of the true pareto front found
- $\beta=$ sucess rate of n-1 points of the true pareto front found and the score become :

$$score = 2\alpha + \beta$$

We then add up the score of each set of parameters accross all the data files to get a final ranking, and we choose the one which got the fewest score.

Randomsearch

Randomsearch

The random search follows the hypergeometric law:

$$X \sim H(N, n, p)$$

with N: populatin size, n: sample size, p: the probability of the issue.

And:

$$P(X = k) = \frac{\binom{Np}{k} \binom{N(1-p)}{n-k}}{\binom{N}{p}}$$

Conclusion

Conclusion

In conclusion to this project, we have realized that metaheuristic algorithms are a promising method for solving complex optimization problems such as the maximization of the $(COP_{DHW}, Stars_float)$. They allowed us to find a solution by exploring roughly a quarter of the design space and win a lot of time for the simulations.
